

Coding exercise – ‘Today I Have’

Summary

Using Ruby on Rails, develop a simple web application that allows users to login and post small updates on what they have been working on today. The user should be able to add one or more ‘tags’ to an update to allow for flexible categorisation.

These updates should be viewable by everyone, and should be able to be filtered by tags.

What we’re looking for

- Clean, concise and well refactored code
 - No 40 line methods!
 - Use Rails helper methods and language features where appropriate
- Well documented code where applicable
 - Document design decisions and major functionality, not single lines of code! If the code is clean then it should be self-explanatory on a line-by-line basis!
- Testing coverage
- Good UI design (in a functional sense, if not in an aesthetic sense)
- Good use of imagination!

Core Deliverables

1. Index that shows all updates organised by/grouped by day
2. Ability to add a new update
 - a. Should require login to post update
 - b. Login/authentication does not have to be comprehensive (i.e. can just check username/password against database). You do not need to provide the ability to add/manage users.
3. Validation, and graceful handling of errors:
 - a. Updates should not be allowed to have the same title/user/date combination
 - b. User should not be able to post more than one update per day
 - c. No field should be allowed to be blank
4. Index that shows all tags and allows you to view updates filed under that tag
5. User should be able to enter new tags when posting an update
 - a. System should have necessary functionality to determine if a tag is new or not
6. Database schema that handles the relationship between updates, tags and users

Bonus points

1. Extend the original spec in an innovative way
2. Use the Bootstrap or similar HTML/CSS framework
3. Use AJAX for posting an update, checking if new updates have been posted, etc
4. Show the new update screen in a modal window rather than on a separate page
5. Allow for filtering updates by user
6. Use of third-party code/frameworks/gems where appropriate
 - a. For example, use the ‘Devise’ gem for authentication
 - b. Bootstrap Rails gem
7. Full functional test coverage
8. Validation wherever you think it might be useful
9. An integration test

10. Code that runs!
11. Javascript UI components where appropriate
 - a. Think about things like the [tag input field](#)...
